

## 1. Fill in blanks. (1×9 points)

- (1) DDL is the language for specifying the database schema and as well as other properties of the data.
- (2) With respect to integrity mechanisms in DBS, trigger defines actions to be executed automatically when some events occur and corresponding conditions are satisfied.
- (3) An entity set that does not have sufficient attributes to form a primary key is termed a weak entity set.
- (4) The commonly-used schemes of organization of records in files are heap file organization, sequential file organization, and hashing file organization.
- (5) The three steps in query processing are parsing and translation, optimization, and evaluation.
- (6) The recovery-management component of a database system implements the support for transaction atomicity and durability.
- (7) A cascadeless schedule ensures that the abort of a transaction does not result in cascading aborts of other transactions.
- (8) The strict two-phase lock protocol requires that all exclusive-mode locks taken by a transaction be held until that transaction commits.
- (9) The three types of failures in DBS are the transaction failures, system crash, and disk failures/crash.

## 2. Choice (1×11 points)

- (1) With respect to DBS design, the index is designed at the D phase.  
A. requirement analysis      B. conceptual design  
C. logical design      D. physical design
- (2) For the E-R diagram given below, the mapping cardinality from *A* to *B* is C

- A. one-to-many    B. one-to-one    C. many-to-one    D. many-to-many
- (3) The following SQL statement corresponds to the expression C.  
**Select    \***  
**From    r, s**  
A.  $r \cap s$       B.  $r \infty s$       C.  $r \times s$       D.  $r - s$
  - (4) Given the schema R(A, B, C, D, E, F) and the functional dependencies  $F = \{AB \rightarrow D, BC \rightarrow E, D \rightarrow F, AB \rightarrow F, CE \rightarrow B\}$  holding on it, D is a transitive functional dependency.

attributes	data types	definitions
<i>c_id</i>	int	unique identifier for the <i>customer</i> ; similar definitions for <i>a_id</i> , <i>p_id</i> , <i>ord_no</i>
<i>c_name</i>	varchar(10)	name of the <i>customer</i> ; similar definitions for <i>a_name</i> and <i>p_name</i>
<i>c_city</i>	varchar(10)	city where the <i>customer</i> is located; similar definitions for <i>a_city</i> and <i>p_city</i>
<i>discount</i>	real	each <i>customer</i> has a negotiated discount (折扣) on prices
<i>quantity</i>	real	quantity of the <i>product</i> on hand for sale, in standard units
<i>price</i>	real	price of each unit product
<i>o_date</i>	date	the year and month the <i>order</i> was placed
<i>qty</i>	real	the total quantity ordered for the <i>product</i>
<i>dollars</i>	real	the cost for the ordered <i>product</i> in this order

Use the SQL statements to implement the following operations:

- (1) Define the table *orders*, it is assumed that the *null* value is inappropriate for the attribute *qty* and the attribute *dollars* ranges from 100 to 10,000. (4 points)
- (2) Find out the *name* of each *customer* who orders all his *products* through only one *agent*. (5 points)
- (3) Give every *customer*, who places some *orders* and the total cost (in *dollars*) of all these *orders* is more than \$2000, a 10% increase in the *discount* he receives. (5 points)
- (4) Create a new table called *Huabei\_customers*, and add into it all *customers* who purchase the *product* “TV” and are located in Beijing, Tianjing and Shijz. (4 points)

Answer:

(1) create table orders(

ord\_no int,

o\_date date,

c\_id int,

a\_id int,

p\_id int,

qty        real        not null,  
dollars    real,  
primary key (ord\_no),  
foreign key (c\_id) references customer,  
foreign key (a\_id) references agents,  
foreign key (p\_id) references products,  
check (dollars between 100 and 10000))

(2) 解法一:

```
select c_name  
from customer,orders  
where customer.c_id = order.c_id  
group by c_id,c_name  
having count(distinct a_id ) = 1
```

解法二:

```
select c_name  
from (select distinct customer. c_name,count (orders.a_id) as agent_number  
      from customer,orders  
      where customer.c_id = orders.c_id  
      group by orders.c_id)  
where agent_number = 1
```

解法三:

```
with cAgent(c_id,a_num) as  
  select c_id,count (distinct a_id)  
  from orders  
  group by c_id  
select c_name  
from customer, cAgent  
where customer.c_id = cAgent.c_id and cAgent.a_num = 1
```

(3) update customer

```
set discount = discount * 1.1
```

```
where c_id in (select c_id  
               from orders  
               group by c_id  
               having sum (dollars) > 2000)
```

(4) 解法一:

```
create table Huabei_customers(  
    c_id      int,  
    c_name    varchar(10),  
    c_city    varchar(10),  
    discount  real;  
    primary key (c_id)  
  
insert into Huabei_customers  
  
    select customer.c_id ,c_name,c_city,discount  
  
    from customer,orders,products  
  
    where customer.c_id = orders.c_id and products.p_id = orders.p_id  
  
    and p_name = 'TV'and p_city in {'Beijing','Tianjing','Shijz'}
```

解法二:

```
create table Huabei_customers(  
    c_id      int,  
    c_name    varchar(10),  
    c_city    varchar(10),  
    discount  real;  
    primary key (c_id)  
  
select customer.c_id ,c_name,c_city,discount  into Huabei_customers  
  
from customer,orders,products
```

where  $\text{customer.c\_id} = \text{orders.c\_id}$  and  $\text{products.p\_id} = \text{orders.p\_id}$

and  $\text{p\_name} = \text{'TV'}$  and  $\text{p\_city}$  in ('Beijing','Tianjing','Shijz')

4. (12 points) The functional dependency set  $F = \{ AB \rightarrow C, A \rightarrow DEI, B \rightarrow FH, F \rightarrow GH, D \rightarrow IJ \}$

holds on the relation schema  $R = (A, B, C, D, E, F, G, H, I, J)$ ,

- Compute  $(AF)^+$  (3 points)
- List all the candidate keys of R. (2 points)
- Compute the canonical cover  $F_c$  (3 points)
- Give a lossless and dependency-preserving decomposition of R into 3NF. (4 points)

Answer:

a. (3 points)

$(AF)^+$  result = AF  
 $A \rightarrow DEI$  result = AFDEI  
 $F \rightarrow GH$  result = AFDEIGH  
 $D \rightarrow IJ$  result = AFDEIGHJ

b. (2 points)

$(AB)^+ = ABCDEFGH$

c. (3 points)

$F_c = \{ AB \rightarrow C, A \rightarrow DE, B \rightarrow F, F \rightarrow GH, D \rightarrow IJ \}$

d. (4 points)

$R_1(A, B, C)$   
 $R_2(A, D, E)$   
 $R_3(D, I, J)$   
 $R_4(B, F)$   
 $R_5(F, G, H)$

5. (20 points) Notown Records company needs to store information about songs, albums and

musicians who perform on its albums in a database. Consider the following information:

- Each musician that records at company has an Id (which is unique), a name, an address, and a phone number.
- Each instrument used in company has a name and an ID, ID is unique.
- Each album recorded on the Notown label has a title, a copyright date, a format, and an album identifier.
- Each song recorded at Notown has a title and an author, and each song can be identified by title.
- Each musician may play several instruments, and a given instrument may be played by several musicians.
- Each album has a number of songs on it, but no song may appear on more than one

album.

- Each song is performed by one or more musicians, and a musician may perform a number of songs.
- Each album has exactly one musician who acts as its producer. A musician may produce several albums, of course.

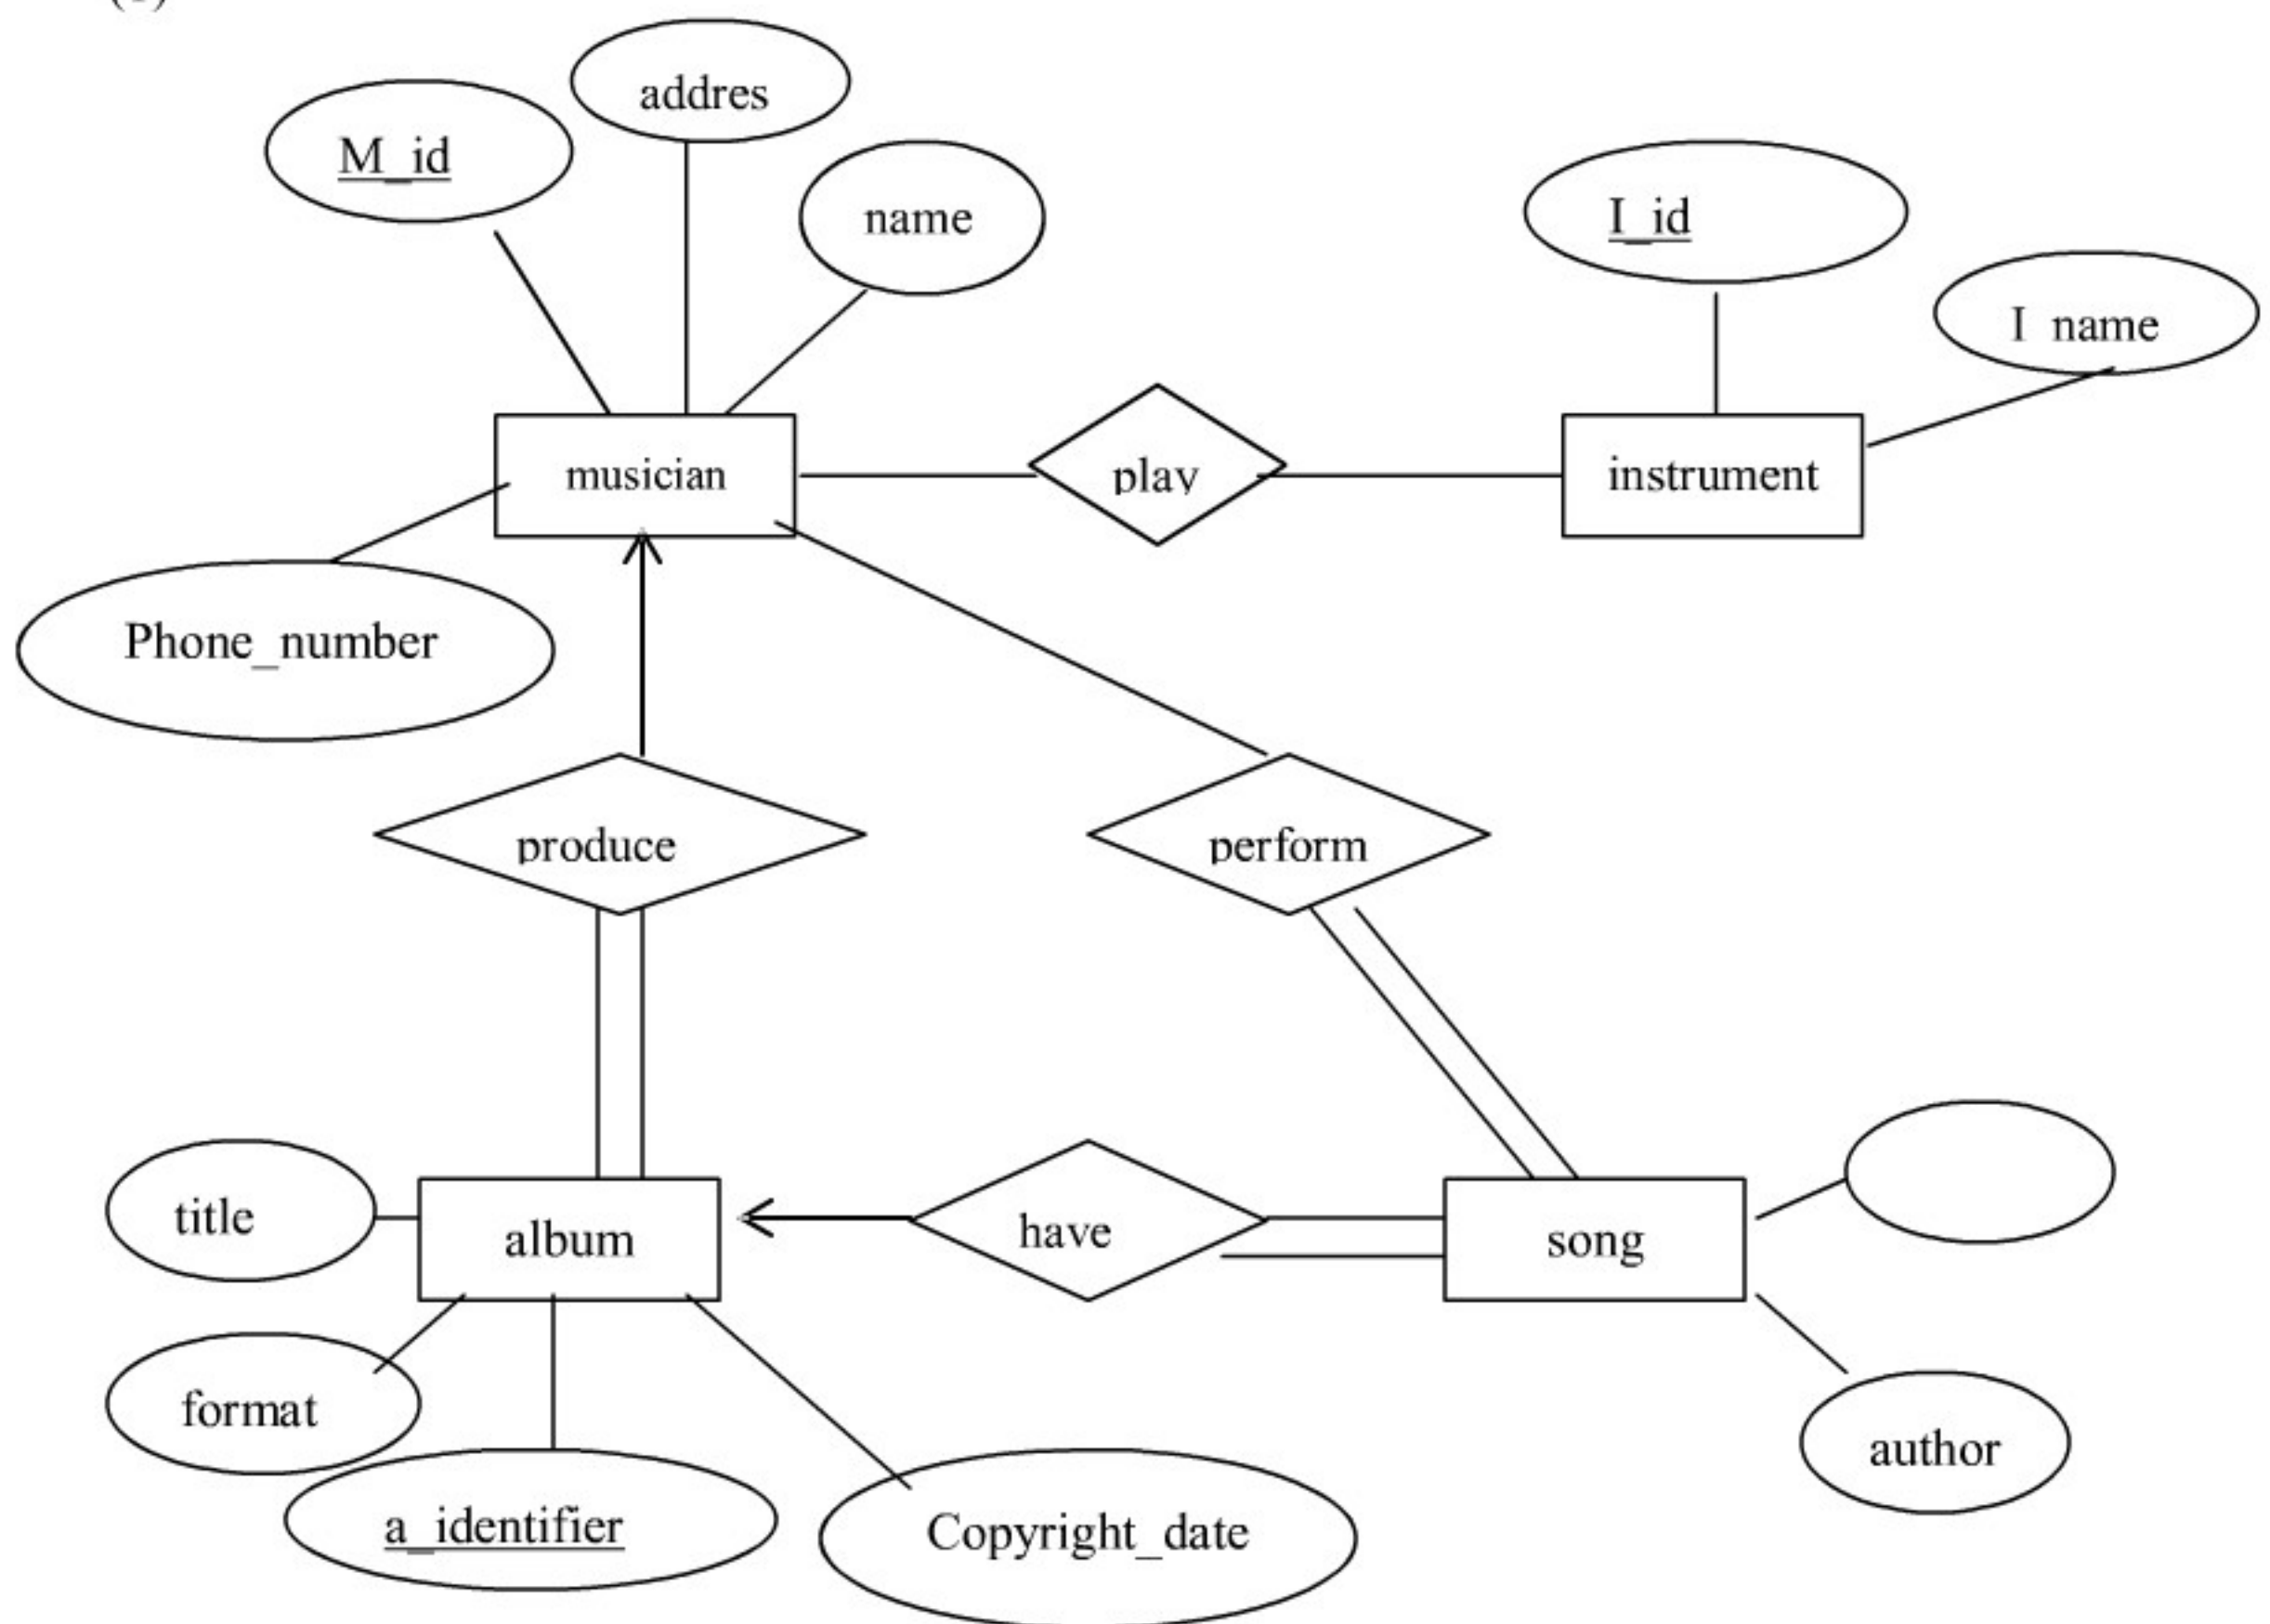

(1) Design the E/R diagram for hospital database on basis of the information mentioned above .(10 points)

*Note:* mapping cardinality of each relationship and participation of each entity to the relationship should be described in the diagram.

(2) Convert the E-R diagram to the proper relational schemas, and give the primary keys of each relation schemas by underlines. (10 points)

Answers:

(1)

全参与和部分参与可有不同答案。

(2) musician(m\_id, name, address, phone\_number)

instrument(I\_id, I\_name)

album(a\_identifier, title, copyright\_date, format, m\_id)

song(s\_title, author, a\_identifier)

play( m\_id, I\_id)

perform(m\_id, s\_title)
